Agenda

Geometry & Load

Fire Scenario

Structural response after fire

Replicability

dataverse.harvard.edu/dataverse/CFT_szymkuc

License:  CC0 - "Public Domain Dedication"

Including:

- presentation
- Abaqus input files
- scripts to handle data

Car park fire

Four-storey 32 x 55 m car park
 16.0 m x 5.0 m parking module
 2.5 m x 5.0 m parking spot
 3.0 m storey height

Typical scenario for columns:

- t = 0 min 1st car ignites
- t = 12 min 2nd and 3rd car ignites
- t = 22 min 4th car ignites

HRR: Schleich et al. (1999)

Car park fire

- A single car is implemented as a cuboid platform with a burning top surface, burning tires and a roof.
- Simple pyrolysis model is used by specifying the HRRPUA. Most of the heat release rate is prescribed to the top of the cuboid platform
- The influence of external weather conditions is not considered
- FDS 6.6.0

CFD-FEM coupling

1. BNDF approach
2. AST GAS approach

Dummy circular AST surfaces:
used with data from BNDF files
(only in Abaqus AST files FDS)

AST GAS devices
facing 0 and 315°
(only in FDS)

concrete-filled steel tube
(Abaqus only)

$$\dot{q}_{tot} = \varepsilon\sigma(T_{AST}^4 - T_{CFT,surface}^4) + h_c(T_{AST} - T_{CFT,surface})$$

CFD-FEM coupling

BNDF approach:

BNDF output is requested:

```
&BNDF QUANTITY='ADIABATIC SURFACE TEMPERATURE' /
```

BNDF temperatures prescribed to “dummy” surface (square)

Heat transfer between two bodies and in solid (CFT) is calculated in Abaqus

Every node of “dummy” surface has a history of AST defined.

CFD-FEM coupling

AST GAS approach:

DEVC output is requested (8 on each height):

&DEVC ID = XXX', QUANTITY='ADIABATIC SURFACE TEMPERATURE GAS'...

DEVC temperatures prescribed to “dummy” surface (circular)

Heat transfer between two bodies and in solid (CFT) is calculated in Abaqus

Every node of “dummy” surface has a history of AST defined.

Part II: Materials: during and after heating

Materials: during and after heating

- During fire exposure:
 - Eurocode properties during heating
- During and after cooling:
 - Steel: fully reversible ($\theta_{\text{steel,max}} = 400^{\circ}\text{C}$)
 - Concrete:
 - thermal & strength properties: non-reversible
 - thermal expansion: reversible
 - Non-reversible properties with USDFLD and UVARM

Temperatures during cooling

Part III:
Column: Thermal and Structural response

AST vs. gas temperature

AST and gas temperature close to the column surface at height $z \approx 1.2$

Highest temperatures at this point:

- gas temperature: 226°C
- AST: 558°C

Temperatures along circumference

600 s:
only car 1 is in fire

1740 s:
all cars are burning,
peak of HRR

Difference between
AST GAS and BNDF
approach are negligible

Temperatures at $z=1.6$ m

Mechanical response

Conclusions

- Coupling between CFD and FEM is presented to provide temperature data around column during both heating and cooling stage
- Abaqus is used to calculate:
 - temperatures inside the column,
 - performance of column during the ISO and localised fireTaking into account non-reversible material properties of concrete
- Although the recorded temperatures are rather low, it is shown that general framework for performance-based approach is established

Numerical investigation of fire and post-fire performance of CFT columns in an open car park fire
